Infant Mortality in Colorado

Why is infant mortality an issue?

Infant mortality refers to the death of an infant before his or her first birthday. Infant mortality rates are often used as indicators of the health and well-being of a nation or state. The infant mortality rate is defined as the number of deaths among all births in one year, expressed as deaths per 1,000 births. In the United States, 25,000 infants die every year, including nearly 400 in Colorado. In 2011, Colorado had 362 deaths out of 65,052 births for a rate of 5.6; the U.S. rate was 6.1. Twelve states have lower infant mortality rates than Colorado. Forty-nine out of over 200 countries have lower infant mortality rates than the United States.

Major causes of infant mortality

Prematurity and related conditions contribute to 38 percent of all infant deaths. Congenital anomalies comprise another 21 percent, and other perinatal conditions contribute 15 percent. Sudden Unexpected Infant Death (SUID) including Sudden Infant Death Syndrome (SIDS), accidental suffocation and strangulation in bed, and undetermined deaths make up 11 percent. Injuries comprise 5 percent and infections contribute 4 percent. All other causes make up the remaining 6 percent. Some causes of death are preventable, while others are more difficult to address. Over the past 10 years, Colorado’s infant mortality rate has been close to the Healthy People 2020 goal of 6.0 deaths per 1,000 births. It met the goal in the two most recent years, 2010 and 2011, as well as in 2001 and 2006.

Healthy People 2020 Goal
By 2020, the infant mortality rate will be reduced to 6.0 deaths per 1,000 births.
Social and economic health disparities

Racial disparity and associated socioeconomic inequality have been identified in the literature as root causes of infant mortality in the United States.7

Infant mortality rates vary by race/ethnicity in Colorado. Infants of color, with the exception of Asian American/Pacific Islander infants, have higher infant mortality rates than White non-Hispanic infants.

Infants of Colorado mothers with less than a high school education have higher infant mortality rates than infants of mothers with college degrees.

Only Larimer County and Douglas County have infant mortality rates that are significantly lower than the Healthy People 2020 goal, which is 6.0 deaths per 1,000 births. All other regions have rates that do not differ from the Healthy People 2020 goal.

Which infants in Colorado have higher mortality rates?

- Infants born to mothers in minority groups
- Infants born to mothers who have less education
What are the components of infant mortality?

Infant mortality is divided into neonatal and postneonatal time frames with different causes associated with each period. Neonatal deaths occur before 28 days of life, while postneonatal deaths occur between 28 and 365 days. Serious congenital anomalies (birth defects), prematurity (birth before 37 completed weeks of gestation) and maternal complications of pregnancy are important contributors to neonatal death. SUID and violent death due to suffocation or homicide are contributors to postneonatal death.

**Neonatal Mortality**
- Seven out of every ten (71%) Colorado deaths occur within 28 days of birth.
- Serious congenital anomalies contribute to one out of every four neonatal deaths.
- Colorado’s neonatal death rate is 4.0 deaths per 1,000 births; the Healthy People 2020 goal is 4.1.

**Postneonatal Mortality**
- Three out of every ten (29%) Colorado infant deaths occur between 28 days and one year of age.
- One out of every seven postneonatal deaths is caused by unintentional injuries.
- Colorado’s postneonatal death rate is 1.6 deaths per 1,000 births; the Healthy People 2020 goal is 2.0.

Are some types of mortality preventable?

Prematurity and congenital anomalies are major contributors to neonatal mortality, but are complex issues to prevent. Some types of sleep-related infant death, however, may be completely preventable.

The drive to reduce SIDS deaths is one example of a national campaign begun in 1994 that reduced SIDS deaths by half in Colorado within six years. Colorado now ranks first among all states for the percentage of infants put to sleep on their backs, with 84 percent put to bed this way in 2010.

Figure 6 shows infant mortality rates in recent years by type of SUID, a category accounting for 10 percent of all infant deaths. The top line combines deaths due to SIDS, undetermined cause of death, and accidental strangulation or suffocation in bed (ASSB); the combined rate in 2011 is just under 0.6 deaths per 1,000 births.

While deaths related to SIDS have decreased, undetermined and ASSB deaths may be increasing slightly due to a shift in how these types of death are classified. A reason for the diagnostic shift may be more thorough death scene investigations, resulting in more deaths being assigned to these categories.
What circumstances surround deaths that occur while infants sleep?

The American Academy of Pediatrics recommends that infants sleep alone on their backs on a firm surface in their cribs. In addition, the Academy recommends that infants sleep in the same room as an adult (room sharing), but that they do not share the same bed. Between 2004 and 2011 a total of 474 Colorado infants died in sleep environments. At least 74 percent (351) of these infants were not placed to sleep according to the Academy recommendations regarding bed sharing, soft bedding and sleep position. Figure 7 shows the identified sleep environment circumstances among these infants.

Bed sharing appears to be an important factor in sleep environment deaths, with 206 infants dying when sharing the bed with another person or persons. Where the circles overlap, two or more circumstances were present: for example, a total of 43 infants died who were sharing a bed and who were put to sleep on their side or stomach. Of the 474 infants who died between 2004 and 2011, only 9 percent (42) met the three major American Academy of Pediatrics recommendations (placed to sleep in a crib or bassinet alone, on their backs, on a firm surface). The sleep environments of 81 infants were unknown.
